

350MHz Fixed Gain Amplifiers with Enable

The EL5106 and EL5306 are fixed gain amplifiers with a bandwidth of 350MHz. This makes these amplifiers ideal for today's high speed video and monitor applications. They feature internal gain setting resistors and can be configured in a gain of +1, -1 or +2.

With a supply current of just 1.5mA and the ability to run from a single supply voltage from 5V to 12V, these amplifiers are also ideal for handheld, portable or battery powered equipment.

The EL5106 and EL5306 also incorporate an enable and disable function to reduce the supply current to 25 μ A typical per amplifier. Allowing the $\overline{\text{CE}}$ pin to float or applying a low logic level will enable the amplifier.

The EL5106 is offered in the 6 Ld SOT-23 and the industry-standard 8 Ld SO packages and the EL5306 is available in the 16 Ld SO and 16 Ld QSOP packages. All operate over the industrial temperature range of -40°C to +85°C.

Features

- Pb-free plus anneal available (RoHS compliant)
- Gain selectable (+1, -1, +2)
- 350MHz -3dB BW ($A_V = 2$)
- 1.5mA supply current per amplifier
- Fast enable/disable
- Single and dual supply operation, from 5V to 12V
- Available in SOT-23 packages
- 450MHz, 3.5mA product available (EL5108 & EL5308)

Applications

- Battery powered equipment
- Handheld, portable devices
- Video amplifiers
- Cable drivers
- RGB amplifiers

Applications Information

Product Description

The EL5106 and EL5306 are fixed gain amplifier that offers a wide -3dB bandwidth of 350MHz and a low supply current of 1.5mA. They work with supply voltages ranging from a single 5V to 12V and they are also capable of swinging to within 1.2V of either supply on the output. These combinations of high bandwidth and low power make the EL5106 and EL5306 the ideal choice for many low-power/high-bandwidth applications such as portable, handheld, or battery-powered equipment.

For varying bandwidth and higher gains, consider the EL5191 with 1GHz on a 9mA supply current or the EL5162 with 300MHz on a 4mA supply current. Versions include single, dual, and triple amp packages with 5 Ld SOT-23, 16-pin QSOP, and 8 Ld or 16 Ld SO outlines.

Power Supply Bypassing and Printed Circuit Board Layout

As with any high frequency device, good printed circuit board layout is necessary for optimum performance. Low impedance ground plane construction is essential. Surface mount components are recommended, but if leaded components are used, lead lengths should be as short as possible. The power supply pins must be well bypassed to reduce the risk of oscillation. The combination of a 4.7μF tantalum capacitor in parallel with a 0.01μF capacitor has been shown to work well when placed at each supply pin.

Disable/Power-Down

The EL5106 and EL5306 amplifiers can be disabled placing their output in a high impedance state. When disabled, the amplifier supply current is reduced to <25μA. The EL5106 and EL5306 are disabled when its $\overline{\text{CE}}$ pin is pulled up to within 1V of the positive supply. Similarly, the amplifier is

enabled by floating or pulling the $\overline{\text{CE}}$ pin to at least 3V below the positive supply. For $\pm 5\text{V}$ supply, this means that the amplifier will be enabled when $\overline{\text{CE}}$ is 2V or less, and disabled when $\overline{\text{CE}}$ is above 4V. Although the logic levels are not standard TTL, this choice of logic voltages allow the EL5106 and EL5306 to be enabled by tying $\overline{\text{CE}}$ to ground, even in 5V single supply applications. The $\overline{\text{CE}}$ pin can be driven from CMOS outputs.

Gain Setting

The EL5106 and EL5306 are built with internal feedback and gain resistors. The internal feedback resistors have equal value; as a result, the amplifier can be configured into gain of +1, -1, and +2 without any external resistors. Figure 13 shows the amplifier in gain of +2 configuration. The gain error is $\pm 2\%$ maximum. Figure 14 shows the amplifier in gain of -1 configuration. For gain of +1, $\text{IN}+$ and $\text{IN}-$ should be connected together as shown in Figure 15. This configuration avoids the effects of any parasitic capacitance on the $\text{IN}-$ pin. Since the internal feedback and gain resistors change with temperature and process, external resistor should not be used to adjust the gain settings.

FIGURE 15. $A_V = -1$ FIGURE 16. $A_V = +1$

Supply Voltage Range and Single-Supply Operation

The EL5106 and EL5306 have been designed to operate with supply voltages having a span of greater than or equal to 5V and less than 11V. In practical terms, this means that the EL5106 and EL5306 will operate on dual supplies ranging from $\pm 2.5\text{V}$ to $\pm 5\text{V}$. With single-supply, the EL5106 and EL5306 will operate from 5V to 10V.

As supply voltages continue to decrease, it becomes necessary to provide input and output voltage ranges that can get as close as possible to the supply voltages. The EL5106 and EL5306 have an input range which extends to within 2V of either supply. So, for example, on $\pm 5\text{V}$ supplies, the EL5106 and EL5306 have an input range which spans $\pm 3\text{V}$. The output range is also quite large, extending to within 1V of the supply rail. On a $\pm 5\text{V}$ supply, the output is therefore capable of swinging from -4V to $+4\text{V}$. Single-supply output range is larger because of the increased negative swing due to the external pull-down resistor to ground. Figure 16 shows an AC-coupled, gain of +2, +5V single supply circuit configuration.

FIGURE 17.

Video Performance

For good video performance, an amplifier is required to maintain the same output impedance and the same frequency response as DC levels are changed at the output. This is especially difficult when driving a standard video load of 150Ω , because of the change in output current with DC level. Previously, good differential gain could only be achieved by running high idle currents through the output transistors (to reduce variations in output impedance). Special circuitries have been incorporated in the EL5106 and EL5306 to reduce the variation of output impedance with current output. This results in dG and dP specifications of 0.02% and 0.04°, while driving 150Ω at a gain of 2.

Output Drive Capability

In spite of its low 1.5mA of supply current per amplifier, the EL5106 and EL5306 are capable of providing a maximum of $\pm 125\text{mA}$ of output current.

Driving Cables and Capacitive Loads

When used as a cable driver, double termination is always recommended for reflection-free performance. For those applications, the back-termination series resistor will decouple the EL5106 and EL5306 from the cable and allow extensive capacitive drive. However, other applications may have high capacitive loads without a back-termination resistor. In these applications, a small series resistor (usually between 5Ω and 50Ω) can be placed in series with the output to eliminate most peaking.

Current Limiting

The EL5106 and EL5306 have no internal current-limiting circuitry. If the output is shorted, it is possible to exceed the Absolute Maximum Rating for output current or power dissipation, potentially resulting in the destruction of the device.

Power Dissipation

With the high output drive capability of the EL5106 and EL5306, it is possible to exceed the 125°C Absolute Maximum junction temperature under certain very high load current conditions. Generally speaking when R_L falls below about 25Ω, it is important to calculate the maximum junction temperature (T_{JMAX}) for the application to determine if power supply voltages, load conditions, or package type need to be modified for the EL5106 and EL5306 to remain in the safe operating area. These parameters are calculated as follows:

$$T_{JMAX} = T_{MAX} + (\theta_{JA} \times n \times PD_{MAX})$$

where:

T_{MAX} = Maximum ambient temperature

θ_{JA} = Thermal resistance of the package

n = Number of amplifiers in the package

PD_{MAX} = Maximum power dissipation of each amplifier in the package

PD_{MAX} for each amplifier can be calculated as follows:

$$PD_{MAX} = (2 \times V_S \times I_{SMAX}) + \left[(V_S - V_{OUTMAX}) \times \frac{V_{OUTMAX}}{R_L} \right]$$

where:

V_S = Supply voltage

I_{SMAX} = Maximum bias supply current

V_{OUTMAX} = Maximum output voltage (required)

R_L = Load resistance
